### Very stable regular G-Higgs bundles

### Miguel González (ICMAT) arXiv:2503.01289

Hitchin–Ngô Laboratory — Special activity ICMAT

June 13th 2025

- *G* connected semisimple complex Lie group, Lie algebra  $\mathfrak{g}$ *X* compact Riemann surface,  $g \ge 2$ , canonical  $K_X$
- A *G*-Higgs bundle  $(E, \varphi)$  over *X*:
  - *E* a principal *G*-bundle over *X*
  - $\varphi$  a holomorphic section of  $E(\mathfrak{g}) \otimes K_X$  (**Higgs field**)

# Moduli space of G-Higgs bundles

- Moduli space of polystable *G*-Higgs bundles  $\mathcal{M}(G)$ .
- *T*<sup>\*</sup>*N*(*G*) ⊆ *M*(*G*) open → symplectic strucutre ω (on smooth locus)
- Hitchin map  $h_G : \mathcal{M}(G) \to \mathcal{A}(G) := \bigoplus_i H^0(C, K_X^{d_i})$ , proper.
- Natural C<sup>×</sup>-action:

$$(E,\varphi)\mapsto (E,\lambda\varphi)$$

• Limits when  $\lambda \rightarrow 0$  exist and are fixed.

#### Definition

The **upward flow** of the fixed point  $(E, \varphi) \in \mathcal{M}(G)^{\mathbb{C}^{\times}}$ :

$$W^+_{(E,\varphi)} := \left\{ (E',\varphi') : \lim_{\lambda \to 0} (E',\lambda\varphi') = (E,\varphi) \right\} \subseteq \mathcal{M}(G)$$

Complex Lagrangian subvarieties (BAA-brane, mirror in  $\mathcal{M}({{G}^{\!\!\vee}}))$ 

### Definition (Hausel-Hitchin, 2022)

Smooth fixed point  $(E, \varphi) \in \mathcal{M}(G)^{s\mathbb{C}^{\times}}$  is **very stable** if  $W_{(E,\varphi)}^{+} \cap h_{G}^{-1}(0) = \{(E,\varphi)\}$ . Equivalently, if  $W_{(E,\varphi)}^{+} \subseteq \mathcal{M}(G)$  is closed. Otherwise, it is **wobbly**.

- Drinfeld and Laumon: E stable G-bundle → (E, 0) very stable
   ⇒ no nonzero nilpotent φ ∈ H<sup>0</sup>(E(𝔅) ⊗ K<sub>X</sub>).
- Motivation: Identifies simplest C<sup>×</sup>-invariant closed complex Lagrangians. h<sub>G</sub> is proper on W<sup>+</sup><sub>(E,φ)</sub>, easier study of mirror.

#### Question

Can we describe which fixed points are very stable?

Take  $G = \operatorname{PGL}_n(\mathbb{C})$  (or  $\operatorname{GL}_n(\mathbb{C})$ ). *E* is a rank *n* vector bundle,  $\varphi : E \to E \otimes K_X$  traceless.

Fixed points are related to **chains**:  $E = \bigoplus_{j=1}^{m} E_j$ ,  $\varphi(E_j) \subseteq E_{j+1} \otimes K_X$ .

$$E_1 \xrightarrow{\varphi_1} E_2 K_X \xrightarrow{\varphi_2} \dots \xrightarrow{\varphi_{m-1}} E_m K_X^{m-1}$$

The **type** of a fixed point is  $(rk E_1, ..., rk E_m)$ .

# Example $G = \operatorname{PGL}_n(\mathbb{C})$ II

Type (n): (E, 0) with *E* stable vector bundle. Nonempty open dense subset of very stable (Laumon, 1988).

Type (1, 1, ..., 1): (Hausel-Hitchin, 2022) Simplest example:

$$E = \mathcal{O} \oplus \mathcal{K}_{X}^{-1} \oplus \dots \oplus \mathcal{K}_{X}^{-n+1}$$

$$\varphi_{0} = \begin{pmatrix} 0 & 0 & \dots & 0 & 0 \\ 1 & 0 & \dots & 0 & 0 \\ 0 & 1 & \dots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & 1 & 0 \end{pmatrix} \qquad \qquad \varphi_{a} = \begin{pmatrix} 0 & 0 & \dots & 0 & -a_{n} \\ 1 & 0 & \dots & 0 & -a_{n-1} \\ 0 & 1 & \dots & 0 & -a_{n-2} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & 1 & 0 \end{pmatrix}$$

for  $a = (a_i)_{i=2}^n \in \mathcal{A}(G)$ .  $(E, \varphi_0)$  is fixed, upward flow is  $\{(E, \varphi_a)\}_a$ **Hitchin section**  $\rightsquigarrow$  very stable.

# Example $G = \operatorname{PGL}_n(\mathbb{C})$ III

In general, fixed points of type  $(1, 1, \dots, 1)$  are

 $E = \mathcal{O} \oplus K_X^{-1}(D_1) \oplus K_X^{-2}(D_1 + D_2) \oplus \cdots \oplus K_X^{-n+1}(D_1 + \cdots + D_{n-1})$ 

$$\varphi = \begin{pmatrix} 0 & 0 & \dots & 0 & 0 \\ \varphi_1 & 0 & \dots & 0 & 0 \\ 0 & \varphi_2 & \dots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & \varphi_{n-1} & 0 \end{pmatrix}$$

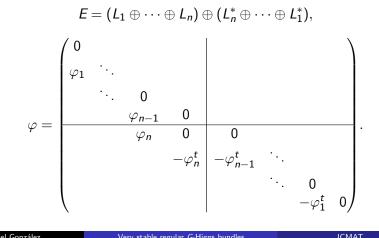

with  $\operatorname{div}(\varphi_j) = D_j$ .

#### Theorem (Hausel–Hitchin, 2022)

Stable fixed point  $(E, \varphi)$  of type (1, 1, ..., 1) is very stable if and only if  $D_1 + \cdots + D_{n-1}$  is reduced.

### Example $G = \operatorname{PGL}_n(\mathbb{C})$ IV and $G = \operatorname{SO}_{2n}(\mathbb{C})$

- Other types: (Peón-Nieto, 2024), e.g. type  $(n_1, n_2) \notin \{(1, 1), (2, 1), (1, 2)\}$  are wobbly.
- Other groups?  $G = SO_{2n}(\mathbb{C})$ . One type is

# Fixed points in $\mathcal{M}(G)$

Fixed points given by  $\mathbb{Z}\text{-}\mathsf{gradings:}$ 

$$\mathfrak{g}=igoplus_{j\in\mathbb{Z}}\mathfrak{g}_j$$

with  $[\mathfrak{g}_j, \mathfrak{g}_k] \subseteq \mathfrak{g}_{j+k}$ .  $[\mathfrak{g}_0, \mathfrak{g}_0] \subseteq \mathfrak{g}_0 \rightsquigarrow G_0 \subseteq G$  connected subgroup.  $[\mathfrak{g}_0, \mathfrak{g}_j] \subseteq \mathfrak{g}_j \rightsquigarrow$  representation  $G_0 \to \mathsf{GL}(\mathfrak{g}_j)$ .

Prop. (Simpson 1988, Biquard–Collier–García-Prada–Toledo, 2023)

Fixed points  $(E, \varphi) \in \mathcal{M}(G)^{\mathbb{C}^{\times}}$  characterised by:

• *E* reduces to  $E_{G_0}$  a  $G_0$ -bundle.

• 
$$arphi \in H^0(\mathsf{E}_{G_0}(\mathfrak{g}_j)\otimes \mathsf{K}_X)$$
 for  $j
eq 0$ 

Called  $(G_0, \mathfrak{g}_j)$ -Higgs pairs.

### Example of $\mathbb{Z}$ -grading

 $G = \operatorname{PGL}_n(\mathbb{C})$ . Gradings of  $\mathfrak{sl}_n(\mathbb{C})$  given by *dividing matrices in blocks* with squares in the diagonal.

( \$0	$\mathfrak{g}_{-1}$		$\mathfrak{g}_{1-m}$	
$\mathfrak{g}_1$	Øо		$\mathfrak{g}_{2-m}$	
:	÷	·	÷	•
$\mathfrak{g}_{m-1}$	$\mathfrak{g}_{m-2}$		۹o /	

I.e. by block size choices  $(n_1, \ldots, n_m)$ .

 $G_0 = \mathrm{P}(\mathrm{GL}_{n_1}(\mathbb{C}) \times \cdots \times \mathrm{GL}_{n_m}(\mathbb{C})) = \mathrm{P}(\mathrm{Aut}(V_1) \times \cdots \times \mathrm{Aut}(V_m))$ 

$$\mathfrak{g}_1 = \bigoplus_{i=1}^{m-1} \operatorname{Hom}(V_i, V_{i+1}).$$

A  $(G_0, \mathfrak{g}_1)$ -Higgs pair precisely defines a chain of type  $(n_1, \ldots, n_m)$ .

Miguel González

Very stable regular G-Higgs bundles

### Question (recall)

Can we describe which fixed points are very stable?

Focus on regular nilpotent Higgs field. These are of Borel type.

#### Definition

Let  $T \subseteq G$  be a maximal torus and  $\Pi = \{\alpha_1, \ldots, \alpha_r\} \subseteq \Delta := \Delta(\mathfrak{g}, \mathfrak{t})$  be a system of simple roots. The **Borel grading** is defined by  $\mathfrak{t} = \mathfrak{g}_0$  and  $\mathfrak{g}_{\alpha_i} \subseteq \mathfrak{g}_1$ .

#### Definition

A fixed point  $(E, \varphi)$  is of **Borel type** if it reduces to  $(G_0, \mathfrak{g}_1)$  for the Borel grading.

# Borel type for $G = \operatorname{PGL}_n(\mathbb{C})$

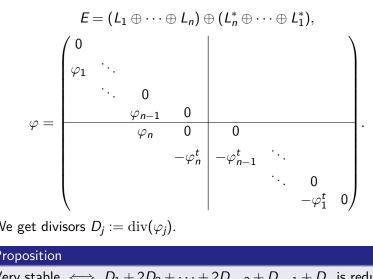

### Take $G = \operatorname{PGL}_n(\mathbb{C})$ .

( \$0	$\mathfrak{g}_{-1}$		$\mathfrak{g}_{1-m}$	
$\mathfrak{g}_1$	Øо		$\mathfrak{g}_{2-m}$	
:	÷	·	÷	
$\mathfrak{g}_{m-1}$	$\mathfrak{g}_{m-2}$		go /	

Borel grading ( $G_0$  a torus) has block sizes (1, 1, ..., 1). Recall:

 $E = \mathcal{O} \oplus \mathcal{K}_X^{-1}(D_1) \oplus \mathcal{K}_X^{-2}(D_1 + D_2) \oplus \dots \oplus \mathcal{K}_X^{-n+1}(D_1 + \dots + D_{n-1})$   $\varphi = \begin{pmatrix} 0 & 0 & \dots & 0 & 0 \\ \varphi_1 & 0 & \dots & 0 & 0 \\ 0 & \varphi_2 & \dots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & \varphi_{n-1} & 0 \end{pmatrix}$ with  $\operatorname{div}(\varphi_j) = D_j$ . Very stable  $\iff D_1 + \dots + D_{n-1}$  reduced (Hausel-Hitchin, 2022).

Borel type for  $G = SO_{2n}(\mathbb{C})$ 

We get divisors  $D_i := \operatorname{div}(\varphi_i)$ .

#### Proposition

Very stable  $\iff D_1 + 2D_2 + \cdots + 2D_{n-2} + D_{n-1} + D_n$  is reduced.

Borel type for  $G = SO_{2n+1}(\mathbb{C})$ 

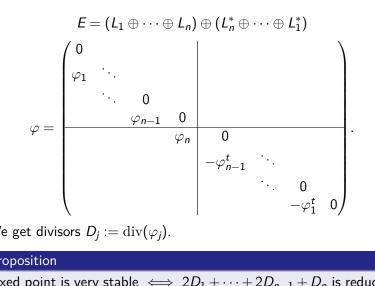

$$\varphi = \begin{pmatrix} L_1 \oplus \cdots \oplus L_n \end{pmatrix} \oplus \mathcal{O}_C \oplus (L_n^* \oplus \cdots \oplus L_1^*), \\ \begin{pmatrix} 0 \\ \varphi_1 & \ddots \\ & \ddots & 0 \\ & \varphi_{n-1} & 0 \\ & & \varphi_n & 0 \\ & & & -\varphi_n^t & 0 \\ & & & & -\varphi_{n-1}^t & \ddots \\ & & & & & \ddots & 0 \\ & & & & & & -\varphi_1^t & 0 \end{pmatrix}.$$

We get divisors  $D_j := \operatorname{div}(\varphi_j)$ .

#### Proposition

Fixed point is very stable  $\iff D_1 + 2D_2 + \cdots + 2D_n$  is reduced.

<u>Borel</u> type for  $G = Sp_{2n}(\mathbb{C})$ 

We get divisors  $D_i := \operatorname{div}(\varphi_i)$ .

#### Proposition

Fixed point is very stable  $\iff 2D_1 + \cdots + 2D_{n-1} + D_n$  is reduced.

# Multiplicity divisor

Why? General phenomenon.

• 
$$\mathfrak{g}_1 = \bigoplus_{\alpha_i \in \Pi} \mathfrak{g}_{\alpha_i}$$

- $G_0 = T \curvearrowright \mathfrak{g}_{\alpha_i}$
- Map E(g<sub>1</sub>) → E(g<sub>αi</sub>) gives φ<sub>i</sub> ∈ H<sup>0</sup>(E(g<sub>αi</sub>) ⊗ K<sub>X</sub>) sections of line bundles.
- Divisors  $D_i := \operatorname{div}(\varphi_i)$ .

**Fundamental coweights**:  $\{\omega_1^{\vee}, \ldots, \omega_r^{\vee}\} \subseteq \mathfrak{t}$ , dual basis to  $\Pi \subseteq \mathfrak{t}^*$ .

### Definition

For a fixed point  $(E, \varphi) \in \mathcal{M}(G)^{\mathbb{C}^{\times}}$  of Borel type, we define its **multiplicity divisor:** 

$$\mu(E,\varphi):=\sum_{i=1}^r D_i\omega_i^{\vee}.$$

Divisor on X whose coefficients are (dominant) coweights.

• There is a **partial ordering** on the space of dominant coweights of g.

 $\lambda \geqslant \mu \iff \lambda-\mu$  is a sum of positive coroots .

• Minimal dominant coweights are called **minuscule**. Representations of  $\mathfrak{g}^\vee$  with a single Weyl orbit of weights.

For example:

- $\mathfrak{g} = \mathfrak{sl}_n(\mathbb{C})$  has the trivial (0) and every *k*-th exterior power of the standard  $(\omega_k^{\vee})$ .
- $\mathfrak{g} = \mathfrak{so}_{2n}(\mathbb{C})$  has the trivial (0), the standard  $(\omega_1^{\vee})$ , and two more  $(\omega_{n-1}^{\vee}, \omega_n^{\vee})$ .
- $E_8, F_4, G_2$  only have the trivial (0).

#### Recall:

- $(E, \varphi) \in \mathcal{M}^{s\mathbb{C}^{\times}}(G)$  smooth fixed point of Borel type.
- $\varphi \rightsquigarrow \varphi_i \rightsquigarrow D_i \rightsquigarrow \mu(E, \varphi)$  a dominant coweight at each point.
- Notion of minimality for dominant coweights.

#### Theorem

Let  $(E, \varphi) \in \mathcal{M}^{s\mathbb{C}^{\times}}(G)$  be a smooth fixed point of Borel type. It is very stable if and only if  $\mu(E, \varphi)|_{x}$  is minuscule at every  $x \in X$ .

- Concrete descriptions in classical groups from before.
- We can say which components (of Borel type) have very stable points. Indeed, the **topological type** of the fixed point in  $\pi_1(G_0) \simeq \mathbb{Z}^r$  is determined by deg  $\mu(E, \varphi) := \sum_{x \in X} \mu(E, \varphi)|_x$ .
- (Hausel-Hitchin, 2022) Every component has very stable points for g = sl<sub>n</sub>(ℂ). Indeed all ω<sup>∨</sup><sub>i</sub> are minuscule in this case.
- Not at all for other g. Extreme case: *E*<sub>8</sub>, *F*<sub>4</sub>, *G*<sub>2</sub> require regularity everywhere.

### Strategy: Hecke transformations

Fixed points of Borel type can be related by **Hecke** transformations. Fix  $x \in X$  and let  $X_0 := X \setminus \{x\}$ .

#### Definition

A Hecke transformation of a *G*-Higgs bundle  $(E, \varphi)$  at *x* is  $(E', \varphi', \psi)$  where  $(E', \varphi')$  is another *G*-Higgs bundle together with an isomorphism

$$\psi: (E', \varphi')|_{X_0} \xrightarrow{\sim} (E, \varphi)|_{X_0}.$$

- Trivialise E over X<sub>0</sub> as well as over a formal disk X<sub>1</sub> ≃ D around x ∈ X.
- Transition function over  $X_{01} := X_0 \cap X_1 \simeq \mathbb{D}^*$ .

$$f_E: X_{01} \to G.$$

i.e. a (meromorphic) loop in G, so  $f_E \in LG$ .

- Hecke transformations: change the transition function  $f_E \in LG$  by  $f_E\sigma$  for a **loop**  $\sigma \in LG$ .
- If  $\sigma \in L^+G$ , i.e. comes from **a disk** in *G*, result is isomorphic. Therefore

$$\left\{ \begin{array}{c} \mathsf{Hecke transformations} \\ \mathsf{of} (\mathsf{E},\mathsf{0}) \mathsf{ at} \mathsf{ x} \end{array} \right\} \leftrightarrow \left\{ \begin{array}{c} \mathsf{points in } \mathsf{affine } \mathsf{Grassmannian} \\ \mathsf{Gr}_{\mathcal{G}} := L\mathcal{G}/L^+\mathcal{G} \end{array} \right)$$

(non canonically). See (Wong, 2013).

# Affine Springer fibre

- What about  $\varphi$ ?
- Locally,  $\varphi_1 : C_1 \to \mathfrak{g}$ , i.e. in  $L^+\mathfrak{g}$ .
- Given  $\sigma \in LG$ , it transforms to  $\operatorname{Ad}_{\sigma^{-1}} \varphi_1 \in L\mathfrak{g}$ , a priori only over  $X_{01}$ .
- We then ask

$$\operatorname{\mathsf{Ad}}_{\sigma^{-1}}\varphi_1\in L^+\mathfrak{g},$$

which defines the affine Springer fibre over  $\varphi_1$ .

 $\left\{ \begin{matrix} \text{Hecke transformations} \\ \text{of } (E, \varphi) \text{ at } x \end{matrix} \right\} \leftrightarrow \left\{ \begin{matrix} \text{points in an affine Springer fibre} \\ \text{given by } \varphi \text{ in } \operatorname{Gr}_{G}. \end{matrix} \right\}.$ 

- $\mathbb{C}^{\times}$ -action on the affine Springer fibre such that if  $\sigma$  gives  $(E', \varphi')$  then  $\lambda \cdot \sigma$  gives  $(E', \lambda \varphi')$ .
- Its fixed points (cocharacters of *T* = *G*<sub>0</sub>) produce C<sup>×</sup>-fixed Higgs bundles.
- Can produce curves between  $\mathbb{C}^{\times}$ -fixed Higgs bundles from curves in the affine Springer fibre.

### Wobbly fixed points

- Consider (E, φ) ∈ M<sup>sC×</sup>(G) smooth fixed point of Borel type with μ(E, φ)|<sub>x</sub> = μ not minuscule.
- There is a positive coroot  $\alpha^{\vee} \in \Delta^{\vee}_+$  with  $\mu \alpha^{\vee}$  dominant.
- In the affine Grassmannian, there is an (explicit) curve connecting the identity and α<sup>∨</sup>.
- Hecke transformation produces curve connecting  $(E, \varphi)$  with  $(E', \varphi')$  such that  $\mu(E', \varphi')|_x = \mu \alpha^{\vee}$ .
- (Key step) Can always choose some α<sup>∨</sup> so that the curve is in the affine Springer fibre and stability is preserved.

- Now  $\mu(E,\varphi)|_x$  is minuscule for all  $x \in X$ .
- Wobbly means there is a C<sup>×</sup>-invariant curve connecting (E, φ) with another fixed point.
- (Key step) This curve comes from Hecke transformation of a similar curve flowing to (E', φ') ∈ M(G)<sup>sC×</sup>, a Hecke transformation of (E, φ) such that μ(E', φ') has smaller support.
- Arrive at the case  $\mu(E, \varphi) = 0$  (everywhere regular  $\varphi$ ) which is very stable.

# Thank you!
